

Cel-Seq primers were used (Hashimshony et al. 2012, PMID: 22939981) to prime RT reaction on mRNA from single cells, containing an Illumina 5' adapter as used in the illumine small RNA kit.

The Illumina 3' adapter from the small RNA kit was then ligated to fragmented amplified RNA, after which the Illumina small RNA kit RT primer was used for cDNA synthesis from the amplified RNA. During PCR, Illumina small RNA kit PCR index primers were used to multiplex libraries into the same sequencing run.

To demultiplex the barcodes after sequencing, read 1 should be parsed in the following manner:

the first 8 basepairs are the Cel-Seq cell barcodes (see list below). The following four basepairs are random basepairs of the unique molecular identifier, which can be used to count individual molecules for each transcript. The rest of read 1 consists of polyT and is not used. Read two is then mapped to the reference genome of choice.
